

Reflection: Where the Agent Adds Genuine Value

What manual test writing could already do well

For only two small feature specifications, an experienced QA engineer could manually write a strong test suite

The agent does ****not**** make human test design obsolete. Human review is still needed for ambiguous requirements

Where the agent genuinely adds value

1. It turns coverage review into a repeatable process

The important contribution is not producing a large CSV. It is maintaining a machine-checkable mapping of requirements to test cases

2. It catches omissions systematically

The critic checks all four required categories, explicit promo rules and quoted error messages. If a case is missing, it is flagged

3. It creates useful boundary scenarios

The repair stage turns natural-language constraints into concrete tests: 7/8/64/65 character passwords, numeric only, etc.

4. It handles state transitions consistently

Scenarios such as login lockout, session expiry/logout, promo replacement, single-use redemption and expiration

5. It produces review evidence

The coverage JSON records each iteration, the gaps found, and the final zero-gap result. That is more than a simple pass/fail

Where the agent adds little value

For a small, stable requirement set, an experienced tester can write the final cases manually in a short time

What I would add next

1. An optional LLM adapter for less structured natural-language requirements.
2. Semantic duplicate detection.
3. Mutation testing: deliberately remove cases and verify the critic detects the loss.
4. Direct TestRail/Zephyr import mappings.
5. A small UI for uploading requirements and downloading suites.
6. More formal risk scoring based on business impact, likelihood and detectability.

Bottom line

The genuine value is the ****generate -> critique -> repair**** workflow. It changes test generation from a one-time task to an ongoing process
